Brief Note

Exclusion of adrenoceptor alpha 2 variants in a horse insensitive to medetomidine

Keywords: Equus caballus, WGS, pharmacogenetics, anaesthesia, adrenergic receptor

Background: Patients may react in different ways to drugs and genetic factors have to be considered when observing variability in drug responses.[1] Drugs acting as agonists for the alpha 2 adrenoceptor (formerly called α_2 adrenergic receptor), such as xylazine, detomidine, medetomidine, or romifidine are regularly used for sedation, premedication and analgesia in veterinary medicine.[2,3] Three genes encode for separate subtypes of alpha 2 adrenoceptors, *ADRA2A*, *ADRA2B,* and *ADRA2C*.[4] Alpha 2 adrenoceptors modulate the regulation of blood pressure, renal function, insulin release, cognition, memory and behaviour.[5] *Adra2a* mutant mice (α_{2A}D79N) are resistant to sedation with dexmedetomidine.[6,7]

Own analysis: A 9-year old Swiss Warmblood horse was presented due to anorexia. Since the horse was highly aggressive, clinical examination was only deemed possible under general anaesthesia. Therefore, tiletamine-zolazepam (2mg/kg) and medetomidine (0.04 mg/kg) were administered intramuscularly by blowpipe darting. While the drug-related side effects such as sweating, polyuria, tremor and ataxia were observed, the sedative effect remained absent. Therefore 35 minutes later a second dart containing tiletamine-zolazepam (1 mg/kg) and medetomidine (0.04 mg/kg) was shot, again without noticeable sedative effects. We sequenced the genome of this horse at 28x coverage as described (study accession PRJEB14779, sample accession SAMEA104357351).[8] We called private variants with respect to 80 genomes from other horses of different horse breeds (Table S1). This analysis yielded 26,416 private variants, 222 of them predicted to be protein-changing (Table S2). During this analysis we recognized that *ADRA2A*, *ADRA2B* and *ADRA2C* contain gaps and/or are not correctly annotated in the current EquCab 2 assembly. Therefore, our automated bioinformatics pipeline for variant detection would not necessarily have detected all possible variants within these genes. Based on preliminary data from the ongoing efforts to produce an EquCab 3 assembly we designed PCR primers for the amplification of the entire *ADRA2A*, *ADRA2B* and *ADRA2C* genes (Table S3). We Sanger sequenced these genes from the medetomidine-resistant horse and a control horse and deposited curated reference sequences for these 3 genes in the European Nucleotide Archive (accessions LT935786 – LT935788). We did not detect any protein-changing variant in the medetomidine-resistant horse.

Comments: Coding variants in *ADRA2A*, *ADRA2B* and *ADRA2C* can be excluded for the observed insensitivity to medetomidine in a Swiss Warmblood horse. We provide new genomic reference sequences for these three genes.

Acknowledgements: We thank Nathalie Besuchet-Schmutz, Muriel Fragnière and Sabrina Schenk for excellent technical assistance. We thank the Next Generation Sequencing Platform of the University of Bern for performing the whole genome sequencing experiment, and the Interfaculty Bioinformatics Unit of the University of Bern for providing high performance computing infrastructure.
